MACSYMA PROGRAM FOR
THE PAINLEVÉ TEST
FOR NONLINEAR ORDINARY
AND PARTIAL DIFFERENTIAL EQUATIONS

Willy Hereman

Mathematics Department
and Center for the Mathematical Sciences
University of Wisconsin at Madison, Wisconsin 53706, USA
Introduction: Mathematical Background

- Roughly speaking, dynamical systems may be divided into two classes:
  1. Systems exhibiting chaotic behavior, i.e. their solutions depend sensitively on the initial data. Such systems are usually **not** explicitly **integrable** in terms of “elementary functions”
  2. Systems that are **algebraically completely integrable**

- Painlevé *et al* identified all second order ODEs of the form $f_{xx} = K(x, f, f_x)$, which are globally integrable in terms of elementary functions by quadratures or by linearization
  The restrictions on the function $K$, which is rational in $f_x$, algebraic in $f$, and analytic in $x$, arise from careful singularity analysis

- Integrability requires that the only **movable singularities** in the solution $f(x)$ are **poles**

- Singularities are **movable** if their location depends on the initial conditions

- **Critical points** (including logarithmic branch points and essential singularities) ought to be fixed to have integrability

- **Definition**: A simple equation or system has the **Painlevé Property (PP)** if its solution in the complex plane has no worse singularities than movable poles

- **For ODEs:**
  1. They admit a finite dimensional Hamiltonian formulation
  2. They have a finite number of first integrals
• For PDEs:

1. Integrability became associated with the existence of a Lax representation which allows \textit{linearization} of the given equation(s) (Inverse Scattering Transform)

2. Ablowitz \textit{et al} conjectured that every ODE, obtained by an exact reduction of a PDE solvable by IST, possesses the PP

3. Similarity transformations reduce them into ODEs of Painlevé type, (e.g. in one of the six Painlevé transcendents)

4. Special ones admit solitary travelling wave solutions (called \textit{solitons} if they conserve their identity upon collision)

5. They possess infinitely many conserved quantities and symmetries, nontrivial prolongation structures, associated Kac-Moody algebras, etc.
2 Algorithm

The algorithm below (Weiss et al.) enables to verify if the ODE or PDE satisfies the necessary criteria to have the PP

- For the PDE case:
  The solution $f$, say in two independent variables $(t, x)$, expressed as a Laurent series,
  \[
  f = g^\alpha \sum_{k=0}^{\infty} u_k g^k
  \] 
  should only have movable poles
  In (1), $u_0(t, x) \neq 0$, $\alpha$ is a negative integer, and $u_k(t, x)$ are analytic functions in a neighborhood of the singular, non-characteristic manifold $g(t, x) = 0$, with $g_x(t, x) \neq 0$

- For the ODE case:
  $x$ will be replaced by $g + x_0$ in (1); $x_0$ being the initial value for $x$
Steps of the Painlevé Test

The Painlevé test is carried out in three steps:

- **Step 1:**
  1. Substitute the leading order term,
     \[ f \propto u_0 g^\alpha \] (2)
     into the given equation
  2. Determine the integer \( \alpha < 0 \) by balancing the minimal power terms
  3. Calculate \( u_0 \)

- **Step 2:**
  1. Substitute the generic terms
     \[ f \propto u_0 g^\alpha + u_r g^{\alpha+r} \] (3)
     into the equation, only retaining its most singular terms
  2. Require that \( u_r \) is arbitrary
  3. Calculate the corresponding values of \( r > 0 \), called **resonances**
• Step 3:

1. Substitute the truncated expansion

\[ f = g^\alpha \sum_{k=0}^{r_{\text{max}}} u_k g^k, \]  

where \( r_{\text{max}} \) represents the largest resonance, into the complete equation.

2. Determine \( u_k \) unambiguously at the non-resonance levels.

3. Check whether or not the **compatibility condition** is satisfied at resonance levels.
4 Remarks

- An equation or system has the Painlevé Property and is conjectured to be integrable if:
  1. Step 1 thru 3 can be carried out consistently with $\alpha < 0$ and with positive resonances,
  2. The compatibility conditions are identically satisfied for all resonances

- For an equation to be integrable it is necessary but not sufficient that it passes the Painlevé test

- Equations for which $\alpha = 0$ deserve special attention

- For some equations, the resonances are complex conjugate, the compatibility being satisfied at real resonance levels

- Quite often the compatibility conditions impose conditions on the coefficients or parameters in the given equation

- The above algorithm does not detect the existence of essential singularities
5 Examples

Example 1: The Korteweg-de Vries Equation
For the ubiquitous KdV equation,

\[ f_t + f f_x + b f_{xxx} = 0, \tag{5} \]

the program provides the following output:

PAINLEVE ANALYSIS OF EQUATION, \( b f_{xxx} + f f_x + f t = 0 \)

SUBSTITUTE \( u_0 g^{\alpha} \) FOR \( f \) IN ORIGINAL EQUATION.
MINIMUM POWERS OF \( g \) ARE \([2 \alpha - 1, \alpha - 3]\)

* COEFFICIENT OF \( g^{2\alpha - 1} \) IS \( u_0^2 \alpha g_x \)
* COEFFICIENT OF \( g^{\alpha - 3} \) IS \( u_0 (\alpha - 2)(\alpha - 1) \alpha b (g_x)^3 \)

FOR EXPONENTS \((2 \alpha - 1)\) AND \((\alpha - 3)\) OF \( g \), DO

WITH \( \alpha = -2 \), POWER OF \( g \) IS \(-5 \) \( \rightarrow \) SOLVE FOR \( u_0 \)
TERM \(-2 u_0 g_x (12 b (g_x)^2 + u_0) \frac{1}{g^5} \) IS DOMINANT
IN EQUATION.

WITH \( u_0 = -12 b (g_x)^2 \) \( \rightarrow \) FIND RESONANCES

\[-9bg_{txxx} (g_x)^3 g_{xx} + (gt)^2 (g_x)^2 g_{xx} + 6(u_4)_x b(g_x)^7 + g_{tt} (g_x)^4\]
\[+2bg_{txxx} (g_x)^4 - 2g_t g_{tx} (g_x)^3)/(6b(g_x)^8)\]

\* COEFFICIENT OF \( g \) IS 0

\( u_6 \) IS ARBITRARY!

COMPATIBILITY CONDITION IS SATISFIED!
Example 2: The sine-Gordon Equation

The transcendental term in the *sine-Gordon* equation, in light cone coordinates,

\[ u_{tx} - \sin(u) = 0, \tag{6} \]

can be removed by the simple substitution \( f = \exp(iu) \) to obtain an equivalent equation with polynomial terms:

\[ -2ff_{t} + 2ff_{tx} - f^{3} + f = 0. \tag{7} \]

---

**Painleve Analysis of Equation**, \(-2ff_{t} + 2ff_{tx} - f^{3} + f = 0\)

**Substitute** \( u_{0} g^{\alpha} \) **for** \( f \) **in original equation.**

**Minimum powers of** \( g \) **are** \([2\alpha - 2, \; 3\alpha, \; \alpha] \)

\* **Coefficient of** \( g^{2\alpha-2} \) **is** \(-2u_{0}^{2} \alpha g_{t}g_{x} \)

\* **Coefficient of** \( g^{3\alpha} \) **is** \(-u_{0}^{3} \)

\* **Coefficient of** \( g^{\alpha} \) **is** \( u_{0} \)

---

**For exponents** \( 2\alpha - 2 \) **and** \( 3\alpha \) **of** \( g \), **do**

**With** \( \alpha \) **for** \( -2 \), **power of** \( g \) **is** \( 6 \) \( \longrightarrow \) **solve for** \( u_{0} \)

**Term** \( u_{0}^{2} (4g_{t}g_{x} - u_{0}) \frac{1}{g_{0}^{6}} \) **is dominant in equation.**

**With** \( u_{0} = 4g_{t}g_{x} \) \( \longrightarrow \) **find resonances**

**Substitute** \( u_{0} g^{\alpha} + u_{r} g^{r+\alpha} \) **for** \( f \) **in equation**

**Term** \( 8(g_{t})^{2}(g_{x})^{2}(r - 2)(r + 1) u_{r} g^{r-6} \) **is dominant in equation.**
THE ONLY NON-NEGATIVE INTEGRAL ROOT IS \([r = 2]\)
WITH MAXIMUM RESONANCE = 2 \(\rightarrow\) CHECK RESONANCES.
SUBSTITUTE POWER SERIES \(\sum_{k=0}^{2} g^{k-2} u_k\) FOR \(f\) IN EQUATION.

WITH \(u_0 = 4g_t g_x\)

\(*\) COEFFICIENT OF \(\frac{1}{g^5}\) IS \(-16(g_t)^2(4g_t x + u_1)(g_x)^2\)

\(u_1 = -4g_t x\)

\(*\) COEFFICIENT OF \(\frac{1}{g^7}\) IS 0

\(u_2\) IS ARBITRARY!

COMPATIBILITY CONDITION IS SATISFIED!

---

FOR EXPONENTS \((2 \alpha - 2)\) AND \((\alpha)\) OF \(g\), \(\alpha = 2\) IS NON-NEGATIVE.

---

FOR EXPONENTS \((3 \alpha)\) AND \((\alpha)\) OF \(g\), \(\alpha = 0\) IS NON-NEGATIVE.
Example 3: The Fisher Equation

From rigorous analysis it follows that if the initial datum is given by
\[ u(0, x) = 1 \quad (x \leq 0), \quad u(0, x) = 0 \quad (x > 0), \]
then the solution of the Fisher equation,
\[ u_t - u_{xx} + u^2 - u = 0, \] (8)
will converge to a travelling wave of speed \( c = 2 \). Furthermore, for every speed \( c \geq 2 \) there is a travelling wave with \( u(t, -\infty) = 1, u(t, \infty) = 0 \).

In 1979, an exact closed form solution of (8) was constructed:
\[ u(t, x) = U(x - x_0 - \frac{5t}{\sqrt{6}}) = U(\xi), \]
where
\[ U(\xi) = \frac{1}{4} \left( 1 - \tanh \left( \frac{\xi}{2\sqrt{6}} \right) \right)^2, \] (9)
with \( x_0 \) any constant.

The Painlevé analysis for (8), put into a travelling frame of reference, exactly determines this particular wave speed \( c = \frac{5}{\sqrt{6}} \), which, indeed, is larger than 2.

*** CHECK FOR FREE PARAMETERS OR PRESENCE OF $u_0$ ***
Example 5: The Fitz Hugh-Nagumo Equation

In 1975 it was found that the Fitz Hugh-Nagumo equation,

$$u_t - u_{xx} - u(1 - u)(u - a) = 0,$$

has a closed form travelling wave solution, $u(t, x) = U(x - x_0 - ct) = U(\xi)$, where

$$U(\xi) = \left(1 + \exp\left(-\frac{\xi}{\sqrt{2}}\right)\right)^{-1} = \frac{1}{2} \left(1 + \tanh\left(\frac{\xi}{2\sqrt{2}}\right)\right),$$

and $c = \frac{2a - 1}{\sqrt{2}}$.

Motivated by the results of the Painlevé analysis, recently two more closed form solutions to the Fitz Hugh-Nagumo equation were found. Both take the form,

$$U(\xi) = \frac{1}{2} \left(A + B \tanh\left(\frac{C\xi}{2\sqrt{2}}\right)\right),$$

where

$A = B = C = a$ \quad for \quad $c = \frac{2 - a}{\sqrt{2}},$

and

$A = 1 + a$ \quad and \quad $B = C = a - 1$ \quad for \quad $c = \frac{-(a + 1)}{\sqrt{2}}.$

Carrying out the Painlevé test for (11), in a travelling frame, leads to a compatibility condition which for $u_0 = \sqrt{2}$ factors into

$$c \left(c - \frac{(2a - 1)}{\sqrt{2}}\right) \left(c + \frac{(a + 1)}{\sqrt{2}}\right) \left(c + \frac{(a - 2)}{\sqrt{2}}\right) = 0.$$

The nonzero roots for $c$ correspond with the wave speeds in (12) and (13). Remark that for $a = \frac{1}{2}$ the wave (12) is stationary ($c = 0$)
PAINLEVE ANALYSIS OF EQUATION, \( f_{xx} + cf_x - f^3 + (a+1)f^2 - af = 0 \)

*** CHECK FOR FREE PARAMETERS OR PRESENCE OF \( u_0 \) ***

---

---
6 Scope and Limitations of the Program

6.1 Scope

- The program works for a single ODE or PDE
- The degree of nonlinearity in all the variables is unlimited
- The number of parameters in the equation is unlimited
- The number of independent variables is also unlimited
- ODEs and PDEs may have explicitly given time/space dependent coefficients of integer degree (see Ex. 4)
- PDEs may have arbitrary time/space dependent coefficients (see Ex. 4)
- Coefficients may be complex, although the usefulness of the Painlevé test is then debatable
- A selected positive or negative rational value of $\alpha$, or $\alpha = 0$ can be supplied
- The time consuming calculation of the coefficients $u_k$ and the verification of the compatibility conditions is optional
- It is possible to substitute an expansion of the form (4) with a selected number of terms, e.g. to carry on with the calculations beyond $r_{max}$
- The output provides vital information, including error messages and warnings, to remedy possible problems
6.2 Limitations

- Systems of equations are excluded.
- The algorithm carries out the traditional Painlevé test based on the expansion (1), with at least rational $\alpha$, hence general fractional expansions in $g$ are excluded.
- Transcendental terms are not allowed. They can often be removed by a suitable transformation of the dependent variable (see Ex. 2).
- Arbitrary parameters in the powers of $f$ and its derivatives are not allowed.
- Neither are arbitrary (unspecified) functions of $f$ and its derivatives.
- Selective substitution of certain $u_k$ is not possible. $u_0$, $u_1$, etc. are explicitly determined whenever possible, and their expressions are used in the calculation of the next $u_k$.
- Nonlinear equations for $u_0$ are not solved. If they occur the program carries on with the undetermined coefficient $u_0$ (see Ex. 5).
- The program only checks if the compatibility condition is identically satisfied. It does not solve for arbitrary parameters (or functions) or for $u_0$ and its derivatives, should these occur (see Exs. 3, 4 and 5).
- Intermediate output is only possible by putting extra `print` statements in the program.
- The expressions occurring in the output on the screen are not accessible for further interactive calculations.
7 Using the Program

The program carries out the Painlevé test in **batch mode** without interaction by the user. The user only has to type in the LHS of the equation and possibly select some options.

- **For ODEs:**
  1. The dependent variable $f$ and independent variable $x$ is mandatory.
  2. A typical term in the ODE reads $fx(.) (x)$, where within the brackets the order of derivation is inserted. The function without derivatives may be denoted by $f$ itself.
  3. The symbol $eq$ denotes the LHS of the equation.
  4. Ex.: To test the Fisher ODE, $f_{xx} + af_x - f^2 + f = 0$, one would enter:
     
     $eq : fx[2](x) + a * f[x](x) + f ** 2 - f$;

     The program will then treat $a$ as an arbitrary parameter.

- **For PDEs:**
  1. A typical term reads $ftxyz[k, l, m, n](t, x, y, z)$, where the integers $k, l, m, n$ are the orders of derivation with respect to the variables $t, x, y,$ and $z$.
  2. Ex.: To test the KdV equation, $f_t + af_x + f_{xxx} = 0$, one enters:
     
     $eq : ftx[1, 0](t, x) + a * f * ftx[0, 1](t, x) + ftx[0, 3](t, x)$;

     Again, the program will treat $a$ as an arbitrary parameter.
Spin-offs of the Painlevé Analysis

- Truncation of the Laurent series (1) at the constant level term leads to auto-Bäcklund or Darboux transformations.
- The resulting Painlevé-Bäcklund equations, obtained by substitution of the truncated expansion and equating to zero powers of \( g \), can be linearized to derive Lax pairs for various ODEs and PDEs.
- As a consequence for ODEs, it is possible to construct algebraic curves and explicitly integrate the equations of motion.
- For PDEs, Painlevé analysis determines the speed of travelling wave solutions (see Exs. 3 and 5).
- It provides insight in the construction of soliton solutions via direct methods (Hirota’s formalism and its clones).
- The Painlevé test helps in identifying the infinite dimensional symmetry algebras for PDEs, which have the structure of subalgebras of Kac-Moody and Virasoro algebras.
