Equipment Fundamentals: Separation & Fractionation

Chapters 4 & 5
With thanks to Tim Rollenhagen, Anadarko
Topics

Fundamentals of separation
  ▪ Volatility differences
    • flash calculations
  ▪ Multi-stage fractionation
    • Distillation
  ▪ Other
    • Adsorption
    • Membranes

Equipment
  ▪ Gas/oil/water separators
    • Filters & coalescers
    • Cyclone separators
  ▪ Distillation columns
    • Auxiliary equipment
      o Condenser
      o Reboiler
    • Trays or packing?
  ▪ Adsorption
    • Mole sieves
  ▪ Membranes
Fundamentals
“Flash calculation” – Description of VLE

Incorporate the mass balance equation with equilibrium constraints

Given a set of equilibrium coefficients, the $K_i$ values, determine the overall molar phase fraction so that the residual equation is equal to zero

- There is a two phase situation if the phase fraction is between 0 and 1
- If the phase fraction is outside this range then there is only a single phase. The phase condition corresponds to the value of $R(0)$ or $R(1)$ that is closer to zero

Can get the expected equations describing the bubble & dew points by setting $\ell=0$ or $\ell=1$

Ideal gas & liquid: $K_i \approx P_i^{\text{vap}}(T) / P$

$$R(\ell) = \sum_{i=1}^{N} \frac{z_i (1-K_i)}{\ell (1-K_i) + K_i} = 0 \text{ with } \ell \equiv \frac{L}{F}$$

or

$$R(\beta) = \sum_{i=1}^{N} \frac{z_i (K_i - 1)}{1 + \beta (K_i - 1)} = 0 \text{ with } \beta \equiv \frac{V}{F}$$
Rackford-Rice Flash Calculation Curves

\[ R(\beta) = \sum_{i=1}^{N} \frac{z_i (K_i - 1)}{1 + \beta (K_i - 1)} = 0 \text{ with } \beta \equiv \frac{V}{F} \]
Entrainment

Small amounts of the coexisting phase gets carried along because of poor physical separation of the phases.

Cannot be predicted from thermodynamics because it is dependent on the flow characteristics of the equipment.
Gravity Settling Theory

Dispersed droplets will settle out from a continuous phase if the gravitational force overcomes the buoyancy & drag forces on the droplets.

The droplet’s terminal velocity typically calculated assuming it is solid, rigid sphere:

\[ V_t = \sqrt{\frac{4gD_p (\rho_p - \rho_c)}{3\rho_c C'}} \]

The drag coefficient can be determined using a definition of Reynolds number based on particle size but fluid properties of the continuous phase:

\[ N_{Re} = \frac{D_p V_t \rho_c}{\mu_c} \]
Drag Coefficient for Spherical Particles

FIG. 7-5
Drag Coefficient and Reynolds Number for Spherical Particles

Ref: GPSA Data Book, 13th ed.
Fractionation as Cascade of Equilibrium Stages

Ref: GPSA Data Book, 13th ed.
Fractionation Key Concepts

Separation due to differences in boiling points/relative volatilities
- Light key & lighter to the overhead
- Heavy key & heavier to the bottoms

Sections
- Rectifying section – heavy key & heavier absorbed into falling liquid
- Stripping section – light key & lighter stripped by rising gas

Heat exchangers may provide vapor & liquid traffic
- Heated bottoms generates vapor for stripping section
- Condenser cools & condenses overhead vapor generating liquid for rectifying section

Ref: GPSA Data Book, 13th ed.
Separation, Reflux, & Number of Stages

During the design phase there is flexibility between the number of stages, the column “traffic” (i.e., reflux, boilup), & the degree of separation

- Trade off between CAPEX & OPEX

Correlations to determine the minimum stages & reflux

- Minimum stages @ infinite/total reflux – Fenske equation
- Minimum reflux @ infinite number of stages – Underwood equation

Typically design to operate at 1.2 to 1.3 times the minimum reflux

- Erbar-Maddox chart to estimate number of stages

Ref: GPSA Data Book, 13th ed.

Other Separation Processes – Adsorption

Molecules get caught up with the adsorbing material allowing the non-adsorbed molecules to pass through with less hindrance.

The retained molecules need to be driven off of the adsorbing material to regenerate the adsorbent.

- PSA – Pressure Swing Adsorption
- TSA – Temperature Swing Adsorption

Separation can be based on molecular size, chemical type, ...
Other Separation Processes – Membranes

Molecules pass through a semi-permeable barrier at different rates

Separation can be based on molecular size, chemical type, ...

http://www.axiom.at/en/gas separationtechnology

Equipment
Types of Separators Used in Gas Processing

Two-Phase Separators:
- Vapor/Liquid
- Liquid/Liquid
- Vapor/Solid
- Liquid/Solid

Three-Phase Separators:
- Vapor/Liquid/Liquid
- Vapor/Liquid/Solid

Ref: GPSA Data Book, 13th ed.
Separation Considerations

Prioritize key parameters to determine separator selection
- Particle/droplet size to be removed
- Pressure drop
- Turndown ability
- Slug handling requirement
- Fouling service
- Gas or liquid controlled
- Ratio of flowrates for each phase
- Design conditions vs. normal operating conditions vs. upset conditions

Performance requirements
- Liquid carry-over specification
- Gas carry-under specification
- Water in hydrocarbon specification
- Oil in water specification
Zones within a separator

Ref: GPSA Data Book, 13th ed.
**Vertical Separators**

Internals can increase separation efficiency & decreases overall size of vessel

- No internals – bulk separation with no obstructions (e.g., flare knock out drum)
- Mesh pad
- Vane packs
- Cyclones
- Combination internals

Ref: GPSA Data Book, 13th ed.
Vertical Gas-Liquid-Liquid Separators

Can do 3-phase separation in a vertical separator – requires baffling to minimize “whirlpool” effect

Ref: GPSA Data Book, 13th ed.
Horizontal Separators

Like a vertical separator, internals can aid in the separation efficiency & lead to small vessels.

Ref: GPSA Data Book, 13th ed.
## Vertical or Horizontal?

* Some horizontal separators, such as a double barrel type, are also good applications for gas dominated services.

**In some applications where small slugs are possible, slugs can be managed in vertical separators.**

Kidnay, Parrish, & McCartney
Separation by centrifugal force

Vortex flow. Heavier particles hit outside walls & fall downward

Can be used to separate liquids and/or solids from gas flow

http://energyeducation.ca/encyclopedia/Cyclone_separator
Sizing of Vertical Separators

When gas flowrate controls sizing:
- Diameter is based on allowable velocity through internal (mesh pad, vane, etc.)
- Height is based on liquid volume requirements and physical height requirements of internals

When liquid flowrate controls sizing:
- Liquid dictates volume requirements
- Height and diameter based on most economic ratio (i.e. L:D of 3)

Fractionation Columns & Trays

Drawings by Henry Padleckas
http://en.wikipedia.org/wiki/Fractionating_column
Fractionation Tray Types

http://www.termoconsult.com/empresas/acs/fractionation_trays.htm
Trays & Packing

Packed towers

Liquid & vapor flow countercurrent through packing
- No specific “tray” or number of “trays”
- A mass transfer zone or “transfer unit” consists of a quantity of packing

Types:
- Random packing
- Structured packing
- Grids

Sizing of tower (diameter) is based on
- Jet flooding (combination of vapor/liquid limit)
- Pressure drop limit (indicates excessive loading)

Typically smaller diameter than trays

Tower Height Calculation

Height based on:
- Number of trays, tray spacing
- Number of packed beds, bed height
- Nozzles and feed internals
- Sump height
- Vapor disengagement
- Manways
- Other internals
  - Chimney trays
  - Bed limiters
  - Redistributors

Ref: GPSA Data Book, 13th ed.
Reboiler considerations

Hydraulics
- Forced circulation
- Natural circulation – most typical

Configuration
- Once through
  - Treat as a stage of separation
- Recirculation

Ref: GPSA Data Book, 13th ed.
Absorption & Stripping

Absorbers: desired component in feed gas
- Absorb a gas phase component (solute) into a liquid (solvent)
- Amine, Selexol, glycol dehydration, etc.

Strippers: desired component in feed liquid
- Strip a dissolved component from liquid into the gas phase
- Sour water, glycol regeneration (stripping gas), etc.

Ref: GPSA Data Book, 13th ed.
Adsorption – Mole Sieve Dehydration

Typically fixed beds with at least two vessels – one in adsorption & one in desorption

Forms of desorption

- TSA – Temperature Swing Adsorption
- PSA – Pressure Swing Adsorption

Ref: GPSA Data Book, 13th ed.
Membrane separation

Typical vessel configurations

- Rolled membrane
- Hollow fiber

http://www.mtrinc.com/faq.html
Summary

Separation of components based on phase equilibrium in separators & fractionators
- Material balance calculation based on a “flash” calculation
- Can further control with adsorbents & membranes

Vessels sized to get the physical separation between vapor & liquid phases
- Internals can greatly increase the separation efficiency leading to smaller vessels

Fractionators can be thought of as cascaded contactors & separators
- Internals may consist of trays and/or packing
