A completely integrable nonlinear partial differential equation (PDE) can be associated with a system of linear PDEs in an auxiliary function whose compatibility requires that the original PDE is satisfied. This associated system is called a Lax pair. Two equivalent representations are presented. The first uses a pair of differential operators which leads to a higher order linear system for the auxiliary function. The second uses a pair of matrices which leads to a first-order linear system. In this paper we present a method, which is easily implemented in Maple or Mathematica, to compute an operator Lax pair for a set of PDEs.

In the operator representation, the determining equations for the Lax pair split into a set of kinematic constraints which are independent of the original equation and a set of dynamical equations which do depend on it. The kinematic constraints can be solved generically. We assume that the operators have a scaling symmetry. The dynamical equations are then reduced to a set of nonlinear algebraic equations.

This approach is illustrated with well-known examples from soliton theory. In particular, it is applied to a three parameter class of fifth-order KdV-like evolution equations which includes the Lax fifth-order KdV, Sawada-Kotera and Kaup-Kuperschmidt equations. A second Lax pair was found for the Sawada-Kotera equation.

Keywords: Lax pair, Lax operator, scaling symmetry, complete integrability, fifth-order KdV-type equations

1. Introduction

The complete integrability of a system of partial differential equations has been a topic of active research over the last forty or so years. Even today there is no one generally accepted definition of integrability. Many approaches have been advocated (see [32] for a recent review), all of which have their merits but none seem to encapsulate the essence of integrability. However one concept has appeared in many different approaches; the Lax pair. This is a reformulation of the original system of nonlinear equations as the compatibility condition for a system of linear equations.

The story of Lax pairs begins with the discovery by Lax [31] of such a linear system for the ubiquitous KdV equation. This equation $[6,28]$ models a variety
*Corresponding author. Email: mark.hickman@canterbury.ac.nz
of nonlinear wave phenomena, including shallow water waves [20] and ion-acoustic waves in plasmas $[1,4,11]$. Lax's discovery shed light on the then newly discovered inverse scattering transform method [16] to solve the KdV equation. It allowed this method to be extended to a variety of integrable equations. In 1979 it was realised that the Lax pair could be interpreted as a zero curvature condition on an appropriate connection [44]. This led to generalisations of the method of inverse scattering transforms. In the 1980s, the algebraic structure of Lax pairs was elucidated. The connection between Lax pairs and Kac-Moody algebras was given in [13]. Subsequent applications for Lax pairs include Bäcklund-Darboux transformations [35], recursion operators [19] and generating integrable hierarchies via the root method [17, 25, 34]. However there was a problem; finding the Lax pair in the first place.

A Lax pair is associated with an infinite hierarchy of local conservation laws; a harbinger of complete integrability (though not all equations with a Lax pair have an infinite set of conservation laws). Exploiting this connection, Wahlquist and Estabrook [14, 40] proposed a method based on pseudopotentials that, in certain circumstances, leads to Lax pairs. However their method leads to a nontrivial problem of finding a representation of a Lie algebra when only a subset of the commutation relations are known.

Another approach to the construction of a Lax pair is provided by singularity analysis. In 1977 it was noted [3] that all symmetry reductions of the classical completely integrable equations result in equations that can be transformed to Painlevé equations. This observation subsequently gave rise to the so-called Painlevé test [41]. In this approach Lax pairs are generated from truncated Painlevé expansions [33]. However the complexity of Painlevé expansion depends critically on the choice of expansion variable.

Computer algebra packages have also been employed to symbolically verify Lax pairs [24, 30]. Of course this requires prior knowledge (or a good guess) of the Lax pair.

In this paper we address the issue of finding Lax pairs, in operator form, for a given system of differential equations by an approach that is amenable to computer algebra. The determining equations for the Lax pair is split into two sets. The first set, the kinematic constraints, are solved generically. The second set, the dynamical equations, depend on the system under consideration. We make the assumption that the system has a scaling symmetry and that this symmetry is inherited by the Lax pair. This allows us to reduce the dynamical equations to an overdetermined system of algebraic equations (nonlinear, naturally). Such systems may then be solved by Gröbner basis techniques.
In the next section, Lax pairs are introduced in their operator representation. In Section 3 the matrix representation of Lax pairs is discussed. The relationship between these two representations is also examined. Section 4 introduces the concept of scaling symmetries. The algorithm to compute Lax pairs based upon scaling symmetries is outlined in the next section. Examples of the algorithm applied to some well-known equations are given in Section 6. Finally the algorithm is used to classify the integrable subcases of a fifth-order KdV-like equation with three parameters. A second Lax pair was found for the Sawada-Kotera equation.

## 2. Lax Pairs in Operator Form

In this paper we consider nonlinear systems of evolution equations in $(1+1)$ dimensions,

$$
\begin{equation*}
\mathbf{u}_{t}=\mathbf{F}\left(\mathbf{u}, \mathbf{u}_{x}, \mathbf{u}_{2 x}, \ldots\right), \tag{1}
\end{equation*}
$$

where $x$ and $t$ are the space and time variables, respectively. The vector $\mathbf{u}(x, t)$ has $N$ components $u_{i}$ and $\mathbf{F}$ is a nonlinear function of its arguments. In the examples we denote the components of $\mathbf{u}$ by $u, v, w, \ldots$. Throughout the paper we use the subscript notation for partial derivatives. If parameters are present in (1), they will be denoted by lower-case Greek letters.

In his seminal paper [31], Lax showed that completely integrable nonlinear PDEs have an associated system of linear PDEs in an auxiliary function $\psi(x, t)$,

$$
\begin{align*}
\mathcal{L} \psi & =\lambda \psi  \tag{2}\\
\psi_{t} & =\mathcal{M} \psi
\end{align*}
$$

where $\mathcal{L}$ and $\mathcal{M}$ are linear differential operators (expressed in powers of the total derivative operator $\mathrm{D}_{x}$ for the space variable $\left.x\right) . \psi$ is an eigenfunction of $\mathcal{L}$ corresponding to eigenvalue $\lambda$. The operators $(\mathcal{L}, \mathcal{M})$ are now known as a Lax pair for (1). The property that (1) is completely integrable is reflected in the fact that the eigenvalues do not change with time which makes the problem isospectral.

Let $G$ be a differential function (functional); that is, a function of $x, t, u$ and partial derivatives of $u$ and let $u_{p, q}=\partial_{x}^{p} \partial_{t}^{q} u$. The total derivatives of $G$ is given by

$$
\begin{align*}
\mathrm{D}_{x} G & =\frac{\partial G}{\partial x}+\sum_{p, q} \frac{\partial G}{\partial u_{p, q}} u_{p+1, q}, \\
\mathrm{D}_{t} G & =\frac{\partial G}{\partial t}+\sum_{p, q} \frac{\partial G}{\partial u_{p, q}} u_{p, q+1} . \tag{3}
\end{align*}
$$

The sums are finite since we will assume that $G$ depends only on finitely many derivatives.

Example 2.1 The KdV equation [1] for $u(x, t)$ can be recast in dimensionless variables as

$$
\begin{equation*}
u_{t}+\alpha u u_{x}+u_{3 x}=0 . \tag{4}
\end{equation*}
$$

The parameter $\alpha$ can be scaled to any real number. Commonly used values are $\alpha= \pm 1$ or $\alpha= \pm 6$. A Lax pair for (4) is given by [31]

$$
\begin{align*}
\mathcal{L} & =\mathrm{D}_{x}^{2}+\frac{1}{6} \alpha u \mathrm{I}  \tag{5}\\
\mathcal{M} & =-4 \mathrm{D}_{x}^{3}-\alpha u \mathrm{D}_{x}-\frac{1}{2} \alpha u_{x} \mathrm{I}
\end{align*}
$$

where $\mathrm{D}_{x}^{n}$ denotes repeated application of $\mathrm{D}_{x}$ ( $n$ times) and I is the identity operator. Substituting $\mathcal{L}$ and $\mathcal{M}$ into (2) yields

$$
\begin{align*}
& D_{x}^{2} \psi=\left(\lambda-\frac{1}{6} \alpha u\right) \psi  \tag{6}\\
& \mathrm{D}_{t} \psi=-4 \mathrm{D}_{x}^{3} \psi-\alpha u \mathrm{D}_{x} \psi-\frac{1}{2} \alpha u_{x} \psi . \tag{7}
\end{align*}
$$

The first equation is a Schrödinger equation for the eigenfunction $\psi$ with eigenvalue $\lambda$ and potential $u(x, t)$. The second equation governs the time evolution of the eigenfunction.

The compatibility condition for the above system is

$$
\begin{equation*}
\mathrm{D}_{t} \mathrm{D}_{x}^{2} \psi-\mathrm{D}_{x}^{2} \mathrm{D}_{t} \psi=\frac{1}{6} \alpha\left(u_{t}+\alpha u u_{x}+u_{3 x}\right) \psi=0 \tag{8}
\end{equation*}
$$

where (6) and (7) are used to eliminate $\mathrm{D}_{t} \psi, \mathrm{D}_{x}^{2} \psi, \mathrm{D}_{x}^{3} \psi$ and $\mathrm{D}_{x}^{5} \psi$. Obviously, (6) and (7) will only be compatible on solutions of (4).

The compatibility of (2) may be expressed directly in terms of the operators $\mathcal{L}$ and $\mathcal{M}$. Indeed

$$
\mathrm{D}_{t}(\mathcal{L} \psi)=\mathcal{L}_{t} \psi+\mathcal{L} \mathrm{D}_{t} \psi=\lambda \mathrm{D}_{t} \psi
$$

where $\mathcal{L}_{t} \psi \equiv \mathrm{D}_{t}(\mathcal{L} \psi)-\mathcal{L} \mathrm{D}_{t} \psi$. Using (2) we have

$$
\mathcal{L}_{t} \psi+\mathcal{L} \mathcal{M} \psi=\lambda \mathcal{M} \psi=\mathcal{M} \lambda \psi=\mathcal{M} \mathcal{L} \psi ;
$$

that is,

$$
\left(\mathcal{L}_{t}+\mathcal{L} \mathcal{M}-\mathcal{M} \mathcal{L}\right) \psi=0
$$

If this operator does not vanish then (2) is not involutive and so would have additional (nonlinear) constraints; that is, one cannot freely specify the initial data for (2). However, if this operator vanishes identically then Lax pair will not encode the original differential equation. Therefore, for a non-trivial Lax pair for (1), this operator must vanish only on solutions of (1). Hence

$$
\begin{equation*}
\mathcal{L}_{t}+[\mathcal{L}, \mathcal{M}] \doteq \mathrm{O} \tag{9}
\end{equation*}
$$

where $\doteq$ denotes that this equality holds only on solutions to the original PDE (1). Here $[\mathcal{L}, \mathcal{M}] \equiv \mathcal{L} \mathcal{M}-\mathcal{M} \mathcal{L}$ is the commutator of the operators and O is the zero operator. Equation (9) is called the Lax equation. Note that $\mathcal{L}_{t}=\left[\mathrm{D}_{t}, \mathcal{L}\right]$ and so the Lax equation takes the form

$$
\begin{equation*}
\left[\mathrm{D}_{t}-\mathcal{M}, \mathcal{L}\right] \doteq \mathrm{O} . \tag{10}
\end{equation*}
$$

Example 2.2 Returning to (5) for the KdV equation, we have

$$
\begin{aligned}
\mathcal{L}_{t} & =\left[\mathrm{D}_{t}, \mathcal{L}\right]=\frac{1}{6} \alpha u_{t} \mathrm{I} \\
\mathcal{L M} & =-4 \mathrm{D}_{x}^{5}-\alpha\left(\frac{5}{3} u \mathrm{D}_{x}^{3}+\frac{5}{2} u_{x} \mathrm{D}_{x}^{2}+\left(\frac{1}{6} \alpha u^{2}+2 u_{x x}\right) \mathrm{D}_{x}+\left(\frac{1}{12} \alpha u u_{x}+\frac{1}{2} u_{3 x}\right) \mathrm{I}\right), \\
\mathcal{M} \mathcal{L} & =-4 \mathrm{D}_{x}^{5}-\alpha\left(\frac{5}{3} u \mathrm{D}_{x}^{3}+\frac{5}{2} u_{x} \mathrm{D}_{x}^{2}+\left(\frac{1}{6} \alpha u^{2}+2 u_{x x}\right) \mathrm{D}_{x}+\left(\frac{1}{4} \alpha u u_{x}+\frac{2}{3} u_{3 x}\right) \mathrm{I}\right)
\end{aligned}
$$

Therefore,

$$
\mathcal{L}_{t}+[\mathcal{L}, \mathcal{M}]=\frac{1}{6} \alpha\left(u_{t}+\alpha u u_{x}+u_{3 x}\right) \text { I, }
$$

which is equivalent to (8).

Various alternatives for the Lax pair operators exist. For example, one could define $\tilde{\mathcal{L}}=\mathcal{L}-\lambda I$ and $\tilde{\mathcal{M}}=\mathcal{M}-\mathrm{D}_{t}$ then (2) becomes $\tilde{\mathcal{L}} \psi=0$ and $\tilde{\mathcal{M}} \psi=0$. The Lax equation (9) is then $[\tilde{\mathcal{L}}, \tilde{\mathcal{M}}] \doteq \mathrm{O}$.

The order of the operator $\mathcal{M}$ may also be reduced. If the order of $\mathcal{L}$ is $\ell$ then any terms $\mathrm{D}_{x}^{\ell+r}$ in $\mathcal{M}$ ( $r$ positive integer) may be rewritten in terms of derivatives of order at most $\ell-1$. Note that this occurs at the expense that the reduced operator $\hat{\mathcal{M}}$ has explicit dependency on the eigenvalue $\lambda$.

Example 2.3 For the KdV equation, using (5), we note that

$$
\begin{equation*}
\mathrm{D}_{x}^{3} \doteq \mathrm{D}_{x}\left[\left(\lambda-\frac{1}{6} \alpha u\right) \mathrm{I}\right]=\left(\lambda-\frac{1}{6} \alpha u\right) \mathrm{D}_{x}-\frac{1}{6} \alpha u_{x} \mathrm{I} \tag{11}
\end{equation*}
$$

and so the third order operator $\mathcal{M}$ is equivalent to

$$
\begin{equation*}
\hat{\mathcal{M}}=-\left(4 \lambda+\frac{1}{3} \alpha u\right) D_{x}+\frac{1}{6} \alpha u_{x} I, \tag{12}
\end{equation*}
$$

which is of first order but depends on $\lambda$.
There is a gauge freedom in the choice of a Lax pair. Suppose $\mathcal{S}$ be an arbitrary but invertible operator and let $\hat{\psi}=\mathcal{S} \psi$. Note that $\lambda \hat{\psi}=\lambda \mathcal{S} \psi=\mathcal{S} \mathcal{L} \psi=\mathcal{S} \mathcal{L S}^{-1} \hat{\psi}$ and

$$
\mathrm{D}_{t} \hat{\psi}=\left[\mathrm{D}_{t}, \mathcal{S}\right] \psi+\mathcal{S} \mathrm{D}_{t} \psi=\left(\left[\mathrm{D}_{t}, \mathcal{S}\right]+\mathcal{S} \mathcal{M}\right) \mathcal{S}^{-1} \hat{\psi}
$$

However, $\left[\mathrm{D}_{t}, \mathcal{S}\right] \mathcal{S}^{-1}=\mathrm{D}_{t}-\mathcal{S} \mathrm{D}_{t} \mathcal{S}^{-1}$ and so $\mathcal{S} \mathrm{D}_{t} \mathcal{S}^{-1} \hat{\psi}=\mathcal{S} \mathcal{M} \mathcal{S}^{-1} \hat{\psi}$. Therefore,

$$
\begin{equation*}
\hat{\mathcal{L}}=\mathcal{S} \mathcal{L S}^{-1}, \quad \hat{\mathcal{M}}=\mathcal{S} \mathcal{M} \mathcal{S}^{-1}, \quad \hat{\mathrm{D}}_{t}=\mathcal{S} \mathrm{D}_{t} \mathcal{S}^{-1} \tag{13}
\end{equation*}
$$

will satisfy $\left[\hat{\mathrm{D}}_{t}-\hat{\mathcal{M}}, \hat{\mathcal{L}}\right] \doteq \mathrm{O}$.

## 3. Lax Pairs in Matrix Form

In [2], Ablowitz et al. introduced a matrix formalism for Lax pairs. Their construction avoids the need to consider higher order Lax operators. They associated matrices $\mathbf{X}$ and $\mathbf{T}$ to the operators $\mathcal{L}$ and $\mathcal{M}$ respectively and considered the system

$$
\begin{align*}
\mathrm{D}_{x} \Psi & =\mathbf{X} \Psi,  \tag{14}\\
\mathrm{D}_{t} \Psi & =\mathbf{T} \Psi
\end{align*}
$$

for an auxiliary vector function $\Psi$. Both $\mathbf{X}$ and $\mathbf{T}$ will be dependent on $\lambda$. The number of components of $\Psi$ is determined by the order of $\mathcal{L}$. When $\mathcal{L}$ is of order $2, \Psi$ has two components and $\mathbf{X}$ and $\mathbf{T}$ are $2 \times 2$ matrices. The compatibility condition for (14) is

$$
\left[\mathrm{D}_{t}, \mathrm{D}_{x}\right] \Psi=\mathrm{D}_{t}(\mathbf{X} \Psi)-\mathrm{D}_{x}(\mathbf{T} \Psi)=\left(\mathrm{D}_{t} \mathbf{X}\right) \Psi+\mathbf{X D}_{t} \Psi-\left(\mathrm{D}_{x} \mathbf{T}\right) \Psi-\mathbf{T D}_{x} \Psi=\mathbf{0}
$$

that is,

$$
\left(\mathrm{D}_{t} \mathbf{X}-\mathrm{D}_{x} \mathbf{T}+[\mathbf{X}, \mathbf{T}]\right) \Psi=\mathbf{0}
$$

where $[\mathbf{X}, \mathbf{T}] \equiv \mathbf{X T}-\mathbf{T X}$ is the matrix commutator. Since we wish to freely specify initial data, the matrix Lax equation follows:

$$
\begin{equation*}
\mathrm{D}_{t} \mathbf{X}-\mathrm{D}_{x} \mathbf{T}+[\mathbf{X}, \mathbf{T}] \doteq \mathbf{0} \tag{15}
\end{equation*}
$$

Geometrically, we may interpret [44] the matrices $\mathbf{X}$ and $\mathbf{T}$ as defining a connection on a vector bundle over the base space given by $(x, t) . \Psi$ is an element of the vector bundle and parallel transport of this element on the base space is given by (14); that is, parallel transport along the $x$-direction is given by $\left(\mathrm{D}_{x}-\mathbf{X}\right) \Psi=\mathbf{0}$ and along the $t$-direction by $\left(\mathrm{D}_{t}-\mathbf{T}\right) \Psi=\mathbf{0}$. Note that

$$
\left[\mathrm{D}_{t}-\mathbf{T}, \mathrm{D}_{x}-\mathbf{X}\right]=\mathrm{D}_{t} \mathbf{X}-\mathrm{D}_{x} \mathbf{T}+[\mathbf{X}, \mathbf{T}] .
$$

Hence, (15) states that the parallel transport of $\Psi$ is independent of the path taken. For this reason (15) is also known as the zero-curvature equation. In particular, we may rewrite (15) as $\left[\nabla_{t}, \nabla_{x}\right] \doteq \mathbf{0}$ where $\nabla_{t} \equiv \mathrm{D}_{t}-\mathbf{T}$ and $\nabla_{x} \equiv \mathrm{D}_{x}-\mathbf{X}$ are the components of the covariant derivative induced by the connection.

Example 3.1 It is well-known that

$$
\mathbf{X}=\left(\begin{array}{cc}
0 & 1  \tag{16}\\
\lambda-\frac{1}{6} \alpha u & 0
\end{array}\right)
$$

and

$$
\mathbf{T}=\left(\begin{array}{cc}
\frac{1}{6} \alpha u_{x} & -4 \lambda-\frac{1}{3} \alpha u  \tag{17}\\
-4 \lambda^{2}+\frac{1}{3} \alpha \lambda u+\frac{1}{18} \alpha^{2} u^{2}+\frac{1}{6} \alpha u_{x x} & -\frac{1}{6} \alpha u_{x}
\end{array}\right)
$$

form a Lax pair for the KdV equation since

$$
\mathrm{D}_{t} \mathbf{X}-\mathrm{D}_{x} \mathbf{T}+[\mathbf{X}, \mathbf{T}]=-\frac{1}{6} \alpha\left(\begin{array}{cc}
0 & 0 \\
u_{t}+\alpha u u_{x}+u_{3 x} & 0
\end{array}\right)
$$

which evaluates to the zero matrix on solutions of (4).
Given an operator Lax pair, $(\mathcal{L}, \mathcal{M})$, finding a corresponding matrix Lax pair, $(\mathbf{X}, \mathbf{T})$, is a straightforward but lengthy computation. As noted above in (11), the operator $\mathcal{L}$ allows one to write higher order derivatives in $x$ in terms of lower order derivatives. Let the order of $\mathcal{L}$ be $\ell$. Without loss of generality, we may assume that the leading coefficient of $\mathcal{L}$ is 1 . Thus,

$$
\begin{equation*}
\mathcal{L}=\mathrm{D}_{x}^{\ell}+f_{\ell-1} \mathrm{D}_{x}^{\ell-1}+\cdots+f_{0} \mathrm{I} . \tag{18}
\end{equation*}
$$

Let

$$
\Psi=\left(\begin{array}{c}
\psi \\
\mathrm{D}_{x} \psi \\
\vdots \\
\mathrm{D}_{x}^{\ell-1} \psi
\end{array}\right)
$$

and so

$$
\mathrm{D}_{x} \Psi=\left(\begin{array}{c}
\mathrm{D}_{x} \psi  \tag{19}\\
\mathrm{D}_{x}^{2} \psi \\
\vdots \\
\mathrm{D}_{x}^{\ell} \psi
\end{array}\right)=\left(\begin{array}{ccccc}
0 & 1 & 0 & \cdots & 0 \\
0 & 0 & 1 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & 1 \\
\lambda-f_{0} & -f_{1} & -f_{2} & \cdots & -f_{\ell-1}
\end{array}\right) \Psi=\mathbf{X} \Psi .
$$

The computation of $\mathbf{T}$ is more elaborate. We have

$$
\mathrm{D}_{t} \Psi=\left(\begin{array}{c}
\psi_{t} \\
\mathrm{D}_{x} \psi_{t} \\
\vdots \\
\mathrm{D}_{x}^{\ell-1} \psi_{t}
\end{array}\right)=\left(\begin{array}{c}
\mathcal{M} \psi \\
\mathrm{D}_{x} \mathcal{M} \psi \\
\vdots \\
\mathrm{D}_{x}^{\ell-1} \mathcal{M} \psi
\end{array}\right)
$$

Note that, using (2) and (18),

$$
\begin{equation*}
\mathrm{D}_{x}^{\ell+r} \psi=-\mathrm{D}_{x}^{r}\left(f_{\ell-1} \mathrm{D}_{x}^{\ell-1}+\cdots+f_{1} \mathrm{D}_{x}+\left(f_{0}-\lambda\right) \mathrm{I}\right) \psi \tag{20}
\end{equation*}
$$

Therefore any derivatives of $\psi$ in $x$ of order $\ell$ or higher are removed by applying (20) recursively. The result is a vector which will depend linearly on $\psi$ and its first $\ell-1$ derivatives; that is $\mathrm{D}_{t} \Psi=\mathbf{T} \Psi$.

We will only show the conversion explicitly for the KdV equation.
Example 3.2 For the KdV equation, (19) reduces to (16). Using (12), we note that

$$
\begin{aligned}
\mathrm{D}_{t} \psi & =\frac{1}{6} \alpha u_{x} \psi-\left(4 \lambda+\frac{1}{3} \alpha u\right) \mathrm{D}_{x} \psi, \\
\mathrm{D}_{t} \mathrm{D}_{x} \psi & =\frac{1}{6} \alpha u_{x x} \psi-\frac{1}{6} \alpha u_{x} \mathrm{D}_{x} \psi-\left(4 \lambda+\frac{1}{3} \alpha u\right) \mathrm{D}_{x}^{2} \psi .
\end{aligned}
$$

However, $\mathrm{D}_{x}^{2} \psi=\left(\lambda-\frac{1}{6} \alpha u\right) \psi$ and so

$$
\mathrm{D}_{t} \mathrm{D}_{x} \psi=\left(-4 \lambda^{2}+\frac{1}{3} \alpha \lambda u+\frac{1}{18} \alpha^{2} u^{2}+\frac{1}{6} \alpha u_{x x}\right) \psi-\frac{1}{6} \alpha u_{x} \mathrm{D}_{x} \psi
$$

Therefore,

$$
\mathrm{D}_{t} \Psi=\left(\begin{array}{cc}
\frac{1}{6} \alpha u_{x} & -4 \lambda-\frac{1}{3} \alpha u \\
-4 \lambda^{2}+\frac{1}{3} \alpha \lambda u \stackrel{1}{18} \alpha^{2} u^{2}+\frac{1}{6} \alpha u_{x x} & -\frac{1}{6} \alpha u_{x}
\end{array}\right) \Psi
$$

which yields $\mathbf{T}$ in (17).
There is gauge freedom in the construction of the matrix representation of a Lax pair. Let $\mathbf{G}$ be a non-singular matrix and $\hat{\Psi}=\mathbf{G} \Psi$. Using (14),

$$
\mathrm{D}_{x} \hat{\Psi}=\mathbf{G D}_{x} \Psi+\mathrm{D}_{x}(\mathbf{G}) \Psi=\left(\mathbf{G X}+\mathrm{D}_{x}(\mathbf{G})\right) \Psi=\left(\mathbf{G} \mathbf{X}+\mathrm{D}_{x}(\mathbf{G})\right) \mathbf{G}^{-1} \hat{\Psi}=\hat{\mathbf{X}} \hat{\Psi}
$$

where

$$
\begin{equation*}
\hat{\mathbf{X}}=\mathbf{G} \mathbf{X} \mathbf{G}^{-1}+\mathrm{D}_{x}(\mathbf{G}) \mathbf{G}^{-1} . \tag{21}
\end{equation*}
$$

Similarly, $\mathrm{D}_{t} \hat{\Psi}=\hat{\mathbf{T}} \Psi$ with

$$
\begin{equation*}
\hat{\mathbf{T}}=\mathbf{G T G}^{-1}+\mathrm{D}_{t}(\mathbf{G}) \mathbf{G}^{-1} . \tag{22}
\end{equation*}
$$

Example 3.3 A second Lax pair [1] for the KdV equation consists of the complex matrices

$$
\hat{\mathbf{X}}=\left(\begin{array}{cc}
-i k & \frac{1}{6} \alpha u  \tag{23}\\
-1 & i k
\end{array}\right)
$$

and

$$
\hat{\mathbf{T}}=\left(\begin{array}{cc}
-4 i k^{3}+\frac{1}{3} i \alpha k u-\frac{1}{6} \alpha u_{x} & \frac{1}{3} \alpha\left(2 k^{2} u-\frac{1}{6} \alpha u^{2}+i k u_{x}-\frac{1}{2} u_{x x}\right)  \tag{24}\\
-4 k^{2}+\frac{1}{3} \alpha u & 4 i k^{3}-\frac{1}{3} i \alpha k u+\frac{1}{6} \alpha u_{x}
\end{array}\right) .
$$

Based on (21) and (22), both Lax pairs are gauge equivalent with

$$
\mathbf{G}=\left(\begin{array}{cc}
-i k & 1 \\
-1 & 0
\end{array}\right)
$$

where $\lambda=-k^{2}$.

## 4. Dilation Invariance of Nonlinear Evolution Equations

Crucial to the computation of Lax pairs is that (9) must hold on the PDE (1). This has the important consequence that any symmetry of the PDE, in particular the dilation symmetry, might be useful to find (9). In other words, we make an ansatz that the operators $\mathcal{L}$ and $\mathcal{M}$ inherit the scaling symmetry from the PDE. This, as it turns out, greatly simplifies the equations that determine the Lax pair.

Example 4.1 The KdV equation (4) is dilation invariant under the scaling symmetry

$$
\begin{equation*}
(t, x, u) \rightarrow\left(\kappa^{-3} t, \kappa^{-1} x, \kappa^{2} u\right) \tag{25}
\end{equation*}
$$

where $\kappa$ is an arbitrary parameter. Indeed, after a change of variables with $\tilde{t}=$ $\kappa^{-3} t, \tilde{x}=\kappa^{-1} x, \tilde{u}=\kappa^{2} u$ and cancellation of a common factor $\kappa^{-5}$, the KdV for $\tilde{u}(\tilde{x}, \tilde{t})$ arises. This dilation symmetry can be expressed as $u \sim \partial_{x}^{2}$ and $\partial_{t} \sim \partial_{x}^{3}$ which means that $u$ scales as two $x$-derivatives and the $t$-derivative scales as three $x$-derivatives.

We define the weight, $W$, of a variable as the exponent of $\kappa$ in the scaling symmetry. It is clear that, from (3), $\mathrm{D}_{x} \sim \partial_{x}$ and $\mathrm{D}_{t} \sim \partial_{t}$ and so we extend weights to operators. For (25), $W(x)=-1$ (or $W\left(\partial_{x}\right)=1$ ), $W(t)=-3$ (or $W\left(\partial_{t}\right)=3$ ) and $W(u)=2$. However we could have scaled each of these weights (effectively $\kappa \rightarrow \kappa^{s}$ ); that is, a scaling symmetry does not uniquely determine a set of weights. We use this freedom to set $W\left(\partial_{x}\right)=1$.

The weight of a monomial is defined as the total weight of the monomial and will also be denoted by $W$. Such monomials may involve the independent and dependent variables and the operators $\partial_{x}, \mathrm{D}_{x}, \partial_{t}$ and $\mathrm{D}_{t}$. In particular, note that $W\left(\mathrm{D}_{x}\right)=W\left(\partial_{x}\right)$ and $W\left(\mathrm{D}_{t}\right)=W\left(\partial_{t}\right)$. An expression (or equation) is uniform in weight if its monomial terms have equal weights. For example, (4) is uniform in weight since each of the three terms has weight 5 .

The importance of uniformity of weight is demonstrated by the KdV equation (4). From (5), it is clear that $\mathcal{L}$ has weight 2 and $\mathcal{M}$ has weight 3 since $W(\mathrm{I})=0$. Therefore this Lax pair inherits the scaling symmetry. Also note that we must assign $W(\lambda)=2$. The elements of the matrices $\mathbf{X}$ and $\mathbf{T}$ in (16) and (17) are also uniform in weight, albeit of different weights. This is also true for the matrices in (23) and (24).

## 5. An algorithm for Computing Lax Pairs in Operator Form

First, one computes the dilation symmetry of the nonlinear PDE and assigns weights such that $W\left(\partial_{x}\right)=1$. Next, one selects the weight $\ell$ of the operator $\mathcal{L}$. Since we have chosen $W\left(\partial_{x}\right)=1, \ell$ will also be the order of $\mathcal{L}$. The minimal weight for $\mathcal{L}$ is the maximum weight of the dependent variables since we want the Lax equation to depend non-trivially on the PDE. It is only through $\mathcal{L}_{t}$ that the $t$-derivatives of the dependent variables appear. Since $\mathcal{L}_{t}=\left[\mathrm{D}_{t}, \mathcal{L}\right], W\left(\mathcal{L}_{t}\right)=W(\mathcal{L})+W\left(\partial_{t}\right)$ and, from (9), $W\left(\mathcal{L}_{t}\right)=W(\mathcal{L})+W(\mathcal{M})$. Thus $W(\mathcal{M})=W\left(\partial_{t}\right)$. Since we require that $\mathcal{M}$ to be a differential operator, we must choose a system of weights such that $W\left(\partial_{t}\right)$ is a non-negative integer.

Thus the candidate Lax pair has the form

$$
\begin{aligned}
\mathcal{L} & =\mathrm{D}_{x}^{\ell}+f_{\ell-1} \mathrm{D}_{x}^{\ell-1}+\cdots+f_{0} \mathrm{l} \\
\mathcal{M} & =c_{m} \mathrm{D}_{x}^{m}+g_{m-1} \mathrm{D}_{x}^{m-1}+\cdots+g_{0} \mathrm{I}
\end{aligned}
$$

where $m=W\left(\partial_{t}\right)$. Now

$$
\begin{equation*}
[\mathcal{L}, \mathcal{M}]=\left(\ell \mathrm{D}_{x} c_{m}\right) \mathrm{D}_{x}^{m+\ell-1}+\cdots . \tag{26}
\end{equation*}
$$

Recall that we require that (9) only holds on solutions of the PDE. Thus the operator $\mathrm{D}_{x}^{m+\ell-1}$ could be reduced to an operator that depends on derivatives of order strictly less than $\ell$. However this would introduce the eigenvalue $\lambda$ and, in this case, there would be a term $\ell \lambda^{m-1} \mathrm{D}_{x} c_{m}$. This would be the only term in $\lambda^{m-1}$. Under the assumption that the operator $\mathcal{L}$ has a complete (and therefore infinite) set of eigenvalues, we conclude $\mathrm{D}_{x} c_{m}=0$; that is, $c_{m}$ is a constant. Therefore (26) becomes

$$
[\mathcal{L}, \mathcal{M}]=\left(\ell \mathrm{D}_{x} g_{m-1}-m c_{m} \mathrm{D}_{x} f_{\ell-1}\right) \mathrm{D}_{x}^{m+\ell-2}+\cdots
$$

After reduction, the coefficient of $\lambda^{m-2}$ must vanish and so

$$
\begin{equation*}
\ell \mathrm{D}_{x} g_{m-1}-m c_{m} \mathrm{D}_{x} f_{\ell-1}=0 \tag{27}
\end{equation*}
$$

In this way, we obtain $m-1$ equations for the unknown coefficient functions $f_{i}, g_{j}$ that do not depend on the PDE. We call these equations kinematic constraints.

The remaining $\ell$ components of (9) may involve terms from $\mathcal{L}_{t}$. When $t$ derivatives do appear, we must use the PDE to remove them. We call these equations dynamical equations.

The kinematic constraints are easily solved. All have the form (27) and so may be solved in terms of the leading $g_{j}$. Specifically, (27) yields

$$
g_{m-1}=\frac{m}{\ell} c_{m} f_{l-1}
$$

In this way, $g_{j}, j=1, \ldots, m-1$, may be written in terms of $g_{0}$ and $f_{i}$. Note that this process does not depend on the PDE and so this rewrite is canonical.

After the elimination of the $g_{j}$, the dynamical equations are a set of ODEs for the remaining coefficient functions $g_{0}$ and $f_{i}$. We now make the ansatz that the terms in the operators $\mathcal{L}$ and $\mathcal{M}$ have uniform weight; that is, $f_{i}$ has weight $\ell-i$ and $g_{0}$ has weight $m$. Thus, for example, $g_{0}$ is assumed to be a linear combination (with unknown coefficients) of monomials of weight $m$. If, in addition, the weights of the dependent variables are positive and the monomials do not depend explicitly on $x$ and $t$, the dynamical equations reduce to an finite system of algebraic equations for the unknown coefficients. This algebraic system (which will also have any parameters that are present in the PDE) is then solved by Gröbner basis methods.
We now illustrate the steps of the algorithm for the KdV equation.

### 5.1. Step 1: Computing the scaling symmetry

The dilation symmetry of (4) can be readily computed by the requirement that (4) is uniform in weight. Indeed, setting $W\left(\partial_{x}\right)=1$, we have

$$
W(u)+W\left(\partial_{t}\right)=2 W(u)+1=W(u)+3,
$$

which yields $W(u)=2$ and $W\left(\partial_{t}\right)=3$. This confirms (25). So, the requirement of uniformity in weight of a PDE allows one to compute the weights of the variables (and thus the scaling symmetry) with linear algebra.

Dilation symmetries, which are special Lie-point symmetries, are common to many nonlinear PDEs. Needless to say, not every PDE is dilation invariant. However non-uniform PDEs can be made uniform by extending the set of dependent variables with auxiliary parameters with appropriate weights. Upon completion of the computations one can set these parameters to 1 .

### 5.2. Step 2: Building a candidate Lax pair

Since $W(u)=2$, the minimal weight for $\mathcal{L}$ is 2 . We therefore choose $\ell=2$. Note, that there is no monomial of weight 1 (any monomial that involves $u$ must have weight at least 2). Therefore we could set $f_{1}=0$. However the kinematic constraints and dynamical equations only depend on the choice of weight for $\mathcal{L}$ and $W\left(\partial_{t}\right)$. So, by not setting $f_{1}=0$ at this stage, we will derive the dynamical equations for all Lax pairs with $\mathcal{L}$ of second order and $W\left(\partial_{t}\right)=3$. Our candidate Lax pair is

$$
\begin{align*}
\mathcal{L} & =\mathrm{D}_{x}^{2}+f_{1} \mathrm{D}_{x}+f_{0} \mathrm{I}  \tag{28}\\
\mathcal{M} & =c_{3} \mathrm{D}_{x}^{3}+g_{2} \mathrm{D}_{x}^{2}+g_{1} \mathrm{D}_{x}+g_{0} \mathrm{I}
\end{align*}
$$

The kinematic constraints (that is, the coefficients of $D_{x}^{3}$ and $D_{x}^{4}$ in $[\mathcal{L}, \mathcal{M}]$ ) give

$$
g_{2}=\frac{3}{2} c_{3} f_{1}, \quad g_{1}=\frac{3}{8} c_{3}\left(2 \mathrm{D}_{x} f_{1}+f_{1}^{2}+4 f_{0}\right) .
$$

Therefore, (28) must have the form

$$
\begin{align*}
\mathcal{L} & =\mathrm{D}_{x}^{2}+f_{1} \mathrm{D}_{x}+f_{0} \mathrm{I}  \tag{29}\\
\mathcal{M} & =c_{3} \mathrm{D}_{x}^{3}+\frac{3}{2} c_{3} f_{1} \mathrm{D}_{x}^{2}+\frac{3}{8} c_{3}\left(2 \mathrm{D}_{x} f_{1}+f_{1}^{2}+4 f_{0}\right) \mathrm{D}_{x}+g_{0} \mathrm{I}
\end{align*}
$$

The dynamical equations are

$$
\begin{align*}
& \mathrm{D}_{t} f_{1}+2 \mathrm{D}_{x} g_{0}-\frac{1}{8} c_{3} \mathrm{D}_{x}\left(2 \mathrm{D}_{x}^{2} f_{1}+12 \mathrm{D}_{x} f_{0}-f_{1}^{3}+12 f_{1} f_{0}\right)=0, \\
& \mathrm{D}_{t} f_{0}+\mathrm{D}_{x}^{2} g_{0}+f_{1} \mathrm{D}_{x} g_{0}  \tag{30}\\
&-c_{3}\left(\mathrm{D}_{x}^{3} f_{0}+\frac{3}{2} f_{1} \mathrm{D}_{x}^{2} f_{0}+\frac{3}{4} \mathrm{D}_{x} f_{1} \mathrm{D}_{x} f_{0}+\frac{3}{8} f_{1}^{2} \mathrm{D}_{x} f_{0}+\frac{3}{2} f_{0} \mathrm{D}_{x} f_{0}\right)=0 .
\end{align*}
$$

Equations (30) are the master equations for (29). In other words, for any equation with a scaling symmetry such that $W\left(\partial_{t}\right)=3$, a Lax pair with a second order eigenvalue problem must have the form (29) where $f_{0}, f_{1}, g_{0}$ and $c_{3}$ satisfy (30).

For the case of the KdV equation, we have $f_{1}=0$ and so (30) reduces to

$$
\begin{aligned}
2 \mathrm{D}_{x} g_{0}-\frac{3}{2} c_{3} \mathrm{D}_{x}^{2} f_{0} & =0, \\
\mathrm{D}_{t} f_{0}+\mathrm{D}_{x}^{2} g_{0}-c_{3}\left(\mathrm{D}_{x}^{3} f_{0}+\frac{3}{2} f_{0} \mathrm{D}_{x} f_{0}\right) & =0
\end{aligned}
$$

Note that, in this case, the first dynamical equation does not depend on the PDE and so may be regarded as a kinematic constraint. This also implies that we cannot set $c_{3}=0$ in order to satisfy the kinematic constraint since this would result in a trivial dynamical equation $\mathrm{D}_{t} f_{0}=0$. Therefore we have $g_{0}=\frac{3}{4} c_{3} \mathrm{D}_{x} f_{0}$ and

$$
\begin{equation*}
\mathrm{D}_{t} f_{0}-\frac{1}{4} c_{3} \mathrm{D}_{x}^{3} f_{0}-\frac{3}{2} c_{3} f_{0} \mathrm{D}_{x} f_{0}=0 \tag{31}
\end{equation*}
$$

Since $f_{0}$ has weight 2 we must have

$$
\begin{equation*}
f_{0}=b_{0} u \tag{32}
\end{equation*}
$$

with $b_{0} \neq 0$.

### 5.3. Step 3: Computing the undetermined coefficients

Equation (32) is substituted into the dynamical equation (31). We obtain

$$
b_{0} u_{t}-c_{3} b_{0} u_{3 x}-\frac{3}{2} c_{3} b_{0}^{2} u u_{x}=0 .
$$

Use (4) to replace $u_{t}$ by $-\left(\alpha u u_{x}+u_{3 x}\right)$ and so

$$
b_{0}\left(\alpha u u_{x}+u_{3 x}+\frac{1}{4} c_{3} u_{3 x}+\frac{3}{2} c_{3} b_{0} u u_{x}\right)=0 .
$$

Equating to 0 the coefficients of the monomials $u_{3 x}$ and $u u_{x}$, we have

$$
b_{0}\left(1+\frac{1}{4} c_{3}\right)=0, \quad b_{0}\left(\alpha+\frac{3}{2} c_{3} b_{0}\right)=0 .
$$

Since $b_{0} \neq 0$, we must have $c_{3}=-4$ and $b_{0}=\frac{1}{6} \alpha$. Finally substitute $f_{0}=\frac{1}{6} \alpha u, f_{1}=$ $0, g_{0}=-\frac{1}{2} \alpha u_{x}$ and $c_{3}=-4$ into (29) to obtain the Lax pair (5). In this case the algebraic system was sufficiently simple that it did not require the machinery of Gröbner bases to solve.

## 6. Examples

The method described in Section 5 can be applied to many nonlinear PDEs in $(1+1)$ dimensions with polynomial nonlinearities. In this section we apply the
method to scalar equations as well as systems. The featured scalar examples are the modified KdV and Boussinesq equations. The method is also illustrated for systems, including a coupled system of KdV equations due to Hirota \& Satsuma and the Drinfel'd-Sokolov-Wilson system.

### 6.1. The modified Korteweg-de Vries equation

For the modified Korteweg-de Vries (mKdV) equation [1] for $u(x, t)$,

$$
\begin{equation*}
u_{t}+\alpha u^{2} u_{x}+u_{3 x}=0, \tag{33}
\end{equation*}
$$

the weights may be chosen to be $W(u)=1, W\left(\partial_{x}\right)=1$, and $W\left(\partial_{t}\right)=3$. Therefore the minimal weight for $\mathcal{L}$ is 1 and the weight of $\mathcal{M}$ is 3 .

Suppose $\mathcal{L}$ has order 1 ; that is,

$$
\begin{align*}
\mathcal{L} & =\mathrm{D}_{x}+f_{0} \mathrm{I}, \\
\mathcal{M} & =c_{3} \mathrm{D}_{x}^{3}+g_{2} \mathrm{D}_{x}^{2}+g_{1} \mathrm{D}_{x}+g_{0} \mathrm{I} \tag{34}
\end{align*}
$$

The kinematic constraints are

$$
\mathrm{D}_{x} g_{2}-3 c_{3} \mathrm{D}_{x} f_{0}=0, \quad \mathrm{D}_{x} g_{1}-3 c_{3} \mathrm{D}_{x}^{2} f_{0}-2 g_{2} \mathrm{D}_{x} f_{0}=0
$$

and so

$$
g_{2}=3 c_{3} f_{0}, \quad g_{1}=3 c_{3}\left(\mathrm{D}_{x} f_{0}+f_{0}^{2}\right)
$$

The dynamical equation is

$$
\mathrm{D}_{t} f_{0}+\mathrm{D}_{x} g_{0}-c_{3} \mathrm{D}_{x}\left(\mathrm{D}_{x}^{2} f_{0}-3 f_{0} \mathrm{D}_{x} f_{0}-f_{0}^{3}\right)=0
$$

In this case, we can replace $g_{0}$ by $g_{0}-c_{3}\left(\mathrm{D}_{x}^{2} f_{0}-3 f_{0} \mathrm{D}_{x} f_{0}-f_{0}^{3}\right)$ to remove $c_{3}$. Thus we can set $c_{3}=0$ without loss of generality. Therefore the Lax pair (34) is

$$
\begin{align*}
\mathcal{L} & =\mathrm{D}_{x}+f_{0} \mathrm{I},  \tag{35}\\
\mathcal{M} & =g_{0} \mathrm{I}
\end{align*}
$$

with the dynamical (that is, master) equation

$$
\mathrm{D}_{t} f_{0}+\mathrm{D}_{x} g_{0}=0
$$

Now assume that $f_{0}$ has weight 1 and $g_{0}$ has weight 3 ; that is

$$
f_{0}=b_{0} u, \quad g_{0}=a_{1} u^{3}+a_{2} u u_{x}+a_{3} u_{x x}
$$

with $b_{0} \neq 0$. The dynamical equation becomes

$$
-b_{0}\left(\alpha u^{2} u_{x}+u_{3 x}\right)+3 a_{1} u^{2} u_{x}+a_{2}\left(u_{x}^{2}+u u_{x x}\right)+a_{3} u_{3 x}=0 .
$$

Setting to zero the coefficients of the monomials $u_{3 x}, u u_{x x}, u_{x}^{2}$ and $u^{2} u_{x}$ yields

$$
a_{3}-b_{0}=0, \quad a_{2}=0, \quad 3 a_{1}-b_{0} \alpha=0
$$

Since $b_{0}$ is free, we can set $b_{0}=1$ and (35) becomes

$$
\begin{align*}
\mathcal{L}_{1} & =\mathrm{D}_{x}+u \mathrm{I}, \\
\mathcal{M}_{1} & =\left(\frac{1}{3} \alpha u^{3}+u_{x x}\right) \mathrm{I} . \tag{36}
\end{align*}
$$

The Lax equation for (36) is the conservation law form of (33).
If we assume that $\mathcal{L}$ has weight 2 , then, since $W\left(\partial_{t}\right)=3$, the Lax pair is given by (29) and the dynamical equations are given by (30). In this case, a gauge on $g_{0}$ will not remove $c_{3}$ from the dynamical equations. The ansatz of uniform weights determines

$$
f_{1}=b_{0} u, \quad f_{0}=b_{1} u^{2}+b_{2} u_{x}, \quad g_{0}=a_{1} u^{3}+a_{2} u u_{x}+a_{3} u_{x x} .
$$

The solution to resultant algebraic system has two branches:

$$
\text { Case I: } \quad \begin{aligned}
& \mathcal{L}= \mathrm{D}_{x}^{2}+2 u \mathrm{D}_{x}+\left(u^{2}+u_{x}\right) \mathrm{I}, \\
& \mathcal{M}= \\
& \text { Case II: } \quad\left(\frac{1}{3} \alpha u^{3}+u_{x x}\right) \mathrm{I} . \\
& \mathcal{L}= \mathrm{D}_{x}^{2}+2 \epsilon u \mathrm{D}_{x}+\frac{1}{6}\left(6 \epsilon^{2} u^{2}+6 \epsilon u_{x}+\alpha u^{2} \pm \sqrt{-6 \alpha} u_{x}\right) \mathrm{I}, \\
& \mathcal{M}=-4 \mathrm{D}_{x}^{3}-12 \epsilon u \mathrm{D}_{x}^{2}-\left(12 \epsilon^{2} u^{2}+12 \epsilon u_{x}+\alpha u^{2} \pm \sqrt{-6 \alpha} u_{x}\right) \mathrm{D}_{x} \\
& \quad-\left(4 \epsilon^{3} u^{3}+\frac{2}{3} \epsilon \alpha u^{3}+12 \epsilon^{2} u u_{x} \pm \epsilon \sqrt{-6 \alpha} u u_{x}+3 \epsilon u_{x x}\right. \\
&\left.\quad+\alpha u u_{x} \pm \frac{1}{2} \sqrt{-6 \alpha} u_{x x}\right) \mathrm{I} .
\end{aligned}
$$

The second case is a 1-parameter family (with parameter $\epsilon$ ) of Lax pairs. This family has the property $\mathcal{M} \rightarrow-4 \mathrm{D}_{x}^{3}$ for solutions of (33) such that $u \rightarrow 0$ as $|x| \rightarrow \infty$. Wadati $[38,39]$ used this property to construct soliton solutions for (33) via the inverse scattering transform from Case II with $\epsilon=0$.

There is one Lax pair with $\mathcal{L}$ of order 3 which is

$$
\begin{aligned}
\mathcal{L} & =\mathrm{D}_{x}^{3}+3 u \mathrm{D}_{x}^{2}+3\left(u^{2}+u_{x}\right) \mathrm{D}_{x}+\left(u^{3}+3 u u_{x}+u_{x x}\right) \mathrm{I}, \\
\mathcal{M} & =\left(\frac{1}{3} \alpha u^{3}+u_{x x}\right) \mathrm{I} .
\end{aligned}
$$

However

$$
\mathcal{L}=\left(\mathrm{D}_{x}+u \mathrm{I}\right)^{3}=\mathcal{L}_{1}^{3}, \quad \mathcal{M}=\mathcal{M}_{1}
$$

where $\mathcal{L}_{1}$ and $\mathcal{M}_{1}$ are given by (36).

### 6.2. The Boussinesq equation

The wave equation,

$$
\begin{equation*}
u_{t t}-u_{x x}+3 u_{x}^{2}+3 u u_{x x}+\alpha u_{4 x}=0, \tag{37}
\end{equation*}
$$

for $u(x, t)$ with real parameter $\alpha$, was proposed by Boussinesq [5] to describe surface waves in shallow water [1]. This equation may be rewritten as a system

$$
\begin{equation*}
u_{t}-v_{x}=0, \quad v_{t}-u_{x}+3 u u_{x}+\alpha u_{3 x}=0, \tag{38}
\end{equation*}
$$

where $v(x, t)$ is an auxiliary dependent variable. We could proceed following the above examples modulo the discussion on scaling below. However we will work directly with (37). First note that (37) can be written as a conservation law,

$$
\begin{equation*}
\mathrm{D}_{t} u_{t}=\mathrm{D}_{x}\left(u_{x}-3 u u_{x}-\alpha u_{3 x}\right) . \tag{39}
\end{equation*}
$$

However it is not uniform in weight (the monomials $u_{x}$ and $u u_{x}$ cannot have the same weight unless $W(u)=0$ ). This problem may be circumvented by the introduction of an auxiliary parameter $\beta$ with an associated weight. Thus, we replace (39) by

$$
\begin{equation*}
\mathrm{D}_{t} u_{t}=\mathrm{D}_{x}\left(\beta u_{x}-3 u u_{x}-\alpha u_{3 x}\right) \tag{40}
\end{equation*}
$$

and assign weights

$$
W\left(\partial_{x}\right)=1, W\left(\partial_{t}\right)=2, W(u)=2 \text { and } W(\beta)=2 .
$$

This example demonstrates that a PDE, which is not dilation invariant, may be expressed in a dilation invariant form by the introduction of auxiliary parameters with weights. Upon completion of the computations, one can set each of these parameters to 1 .

The "fundamental" dependent variable in this equation is $u_{t}$ (that is, $u_{t t}=\mathrm{D}_{t} u_{t}$ ). However the Boussinesq equation is a conservation law. Therefore we can use $\mathrm{D}_{x}^{-1} u_{t}$ as a fundamental variable; in other words, rewrite (40) as

$$
\mathrm{D}_{t}\left(\mathrm{D}_{x}^{-1} u_{t}\right)=\beta u_{x}-3 u u_{x}-\alpha u_{3 x} .
$$

Therefore the minimal order of $\mathcal{L}$ is 3 . Since there are no weight 1 monomials, the minimal order Lax pair is given by

$$
\begin{aligned}
\mathcal{L} & =\mathrm{D}_{x}^{3}+f_{1} \mathrm{D}_{x}+f_{0} \mathrm{I}, \\
\mathcal{M} & =c_{2} \mathrm{D}_{x}^{2}+g_{0} \mathrm{l}
\end{aligned}
$$

The kinematic constraint is $3 \mathrm{D}_{x} g_{0}=2 c_{2} \mathrm{D}_{x} f_{1}$ which gives

$$
g_{0}=\frac{2}{3} c_{2} f_{1}+c_{0} \beta .
$$

The extra term arises since the constant $\beta$ has weight 2 . The dynamical equations become

$$
\begin{align*}
& \mathrm{D}_{t} f_{1}=c_{2}\left(2 \mathrm{D}_{x} f_{0}-\mathrm{D}_{x}^{2} f_{1}\right),  \tag{41}\\
& \mathrm{D}_{t} f_{0}=c_{2}\left(\mathrm{D}_{x}^{2} f_{0}-\frac{2}{3} \mathrm{D}_{x}^{3} f_{1}-\frac{2}{3} f_{1} \mathrm{D}_{x} f_{1}\right) .
\end{align*}
$$

Since it is $u_{t t}$ and not $u_{t}$ that appears in (40), derivatives of $u$ that have at most only one $t$-derivative may be freely specified in the initial data for (40). Thus $u_{t}, u_{x t}, u_{x x t}, \ldots$ may appear in monomials used to construct $f_{0}$ and $f_{1}$. In addition, $f_{0}$ only appears in the right hand side of the dynamical equations in the form $\mathrm{D}_{x} f_{0}$. Thus a non-local term of the form $\mathrm{D}_{x}^{-1} f$, where $f$ has weight 4, may appear in $f_{0}$.

Consequently, the weight ansatz implies

$$
\begin{aligned}
& f_{1}=a_{1} u+a_{2} \beta, \\
& f_{0}=a_{3} u_{x}+\mathrm{D}_{x}^{-1}\left(a_{4} u^{2}+a_{5} \beta u+a_{6} u_{t}+a_{7} \beta^{2}\right) .
\end{aligned}
$$

Under this ansatz, the dynamical equation (41) becomes the kinematic constraint

$$
\begin{equation*}
a_{1} u_{t}=2 c_{2}\left(a_{3} u_{x x}+a_{4} u^{2}+a_{5} \beta u+a_{6} u_{t}+a_{7} \beta^{2}-\frac{1}{2} a_{1} u_{x x}\right) . \tag{42}
\end{equation*}
$$

For a non-trivial solution, we require $a_{1} \neq 0$ and so $c_{2} \neq 0$. Thus $a_{4}=a_{5}=a_{7}=0$, $a_{1}=2 c_{2} a_{6}$ and $a_{3}=c_{2} a_{6}$. Hence,

$$
\mathrm{D}_{t} f_{0}=a_{3} u_{x t}+a_{6} \mathrm{D}_{x}^{-1} u_{t t} \doteq a_{6}\left(c_{2} u_{x t}+\beta u_{x}-3 u u_{x}-\alpha u_{3 x}\right)
$$

on solutions of (40). Therefore the remaining dynamical equation is

$$
a_{6}\left(c_{2} u_{x t}+\beta u_{x}-3 u u_{x}-\alpha u_{3 x}\right)=c_{2} a_{6}\left(u_{x t}-\frac{1}{3} c_{2} u_{3 x}-\frac{4}{3} c_{2} u_{x}\left(2 c_{2} a_{6} u+a_{2} \beta\right)\right) .
$$

The solution of this equation gives the Lax pair

$$
\begin{aligned}
\mathcal{L} & =\mathrm{D}_{x}^{3}+\frac{1}{4 \alpha}(3 u-\beta) \mathrm{D}_{x}+\frac{3}{8 \alpha^{2}}\left(\alpha u_{x} \pm \frac{1}{3} \sqrt{3 \alpha} \mathrm{D}_{x}^{-1} u_{t}\right) \mathrm{I}, \\
\mathcal{M} & = \pm \sqrt{3 \alpha} \mathrm{D}_{x}^{2} \pm \frac{\sqrt{3 \alpha}}{2 \alpha} u \mathrm{I} .
\end{aligned}
$$

The subcase $\beta=1$ is a Lax pair for (37) [43]. Note that the auxiliary variable $v$ that was introduced to obtain the system (38) is, in fact, $\mathrm{D}_{x}^{-1} u_{t}$. A Lax pair for the system is obtained by replacing $\mathrm{D}_{x}^{-1} u_{t}$ by $v$.

### 6.3. The coupled Korteweg-de Vries equations

The coupled Korteweg-de Vries (cKdV) equations [21],

$$
\begin{equation*}
u_{t}-6 \beta u u_{x}+6 v v_{x}-\beta u_{3 x}=0, \quad v_{t}+3 u v_{x}+v_{3 x}=0 \tag{43}
\end{equation*}
$$

where $\beta$ is a nonzero parameter, describes interactions of two waves with different dispersion relations. System (43) is known in the literature as the Hirota-Satsuma system. It is completely integrable $[1,21]$ when $\beta=\frac{1}{2}$.

We assign the weights $W\left(\partial_{x}\right)=1, W\left(\partial_{t}\right)=3, W(u)=2$ and $W(v)=2$. Since $W\left(\partial_{t}\right)=3$ and there are no weight 1 monomials, the dynamical equations are precisely those of the KdV equation (4). The minimal weight for $\mathcal{L}$ is 2 and so the dynamical equation is (31) with

$$
f_{0}=b_{0} u+b_{1} v
$$

The resultant equations have only a trivial solution. Likewise, there are also no Lax pairs with $\mathcal{L}$ of third order.

For the case $W(\mathcal{L})=4$, the candidate Lax pair, after the kinematic constraints
have been solved, is

$$
\begin{aligned}
\mathcal{L} & =\mathrm{D}_{x}^{4}+f_{2} \mathrm{D}_{x}^{2}+f_{1} \mathrm{D}_{x}+f_{0} \mathrm{I} \\
\mathcal{M} & =c_{3} \mathrm{D}_{x}^{3}+\frac{3}{4} c_{3} f_{2} \mathrm{D}_{x}+\frac{3}{8} c_{3}\left(2 f_{1}-\mathrm{D}_{x} f_{2}\right) ।
\end{aligned}
$$

with dynamical equations

$$
\begin{aligned}
& \mathrm{D}_{t} f_{2}+\frac{1}{4} c_{3}\left(6 \mathrm{D}_{x}^{2} f_{1}-\mathrm{D}_{x}^{3} f_{2}+3 f_{2} \mathrm{D}_{x} f_{2}-12 \mathrm{D}_{x} f_{0}\right)=0, \\
& \mathrm{D}_{t} f_{1}+\frac{1}{4} c_{3}\left(8 \mathrm{D}_{x}^{3} f_{1}-3 \mathrm{D}_{x}^{4} f_{2}+3 f_{2} \mathrm{D}_{x} f_{1}+3 f_{1} \mathrm{D}_{x} f_{2}-12 \mathrm{D}_{x}^{2} f_{0}\right)=0, \\
& \mathrm{D}_{t} f_{0}+\frac{1}{8} c_{3}\left(6 \mathrm{D}_{x}^{4} f_{1}-3 \mathrm{D}_{x}^{5} f_{2}+6 f_{2} \mathrm{D}_{x}^{2} f_{1}-3 f_{2} \mathrm{D}_{x}^{3} f_{2}\right. \\
&\left.+6 f_{1} \mathrm{D}_{x} f_{1}-3 f_{1} \mathrm{D}_{x}^{2} f_{1}-8 \mathrm{D}_{x}^{3} f_{0}-6 f_{2} \mathrm{D}_{x} f_{0}\right)=0 .
\end{aligned}
$$

A non-trivial solution exists only when $\beta=\frac{1}{2}$. In this case the solution is

$$
\begin{aligned}
\mathcal{L} & =\mathrm{D}_{x}^{4}+2 u \mathrm{D}_{x}^{2}+2\left(u_{x}-v_{x}\right) \mathrm{D}_{x}+\left(u^{2}-v^{2}+u_{2 x}-v_{2 x}\right) \mathrm{I}, \\
\mathcal{M} & =2 \mathrm{D}_{x}^{3}+3 u \mathrm{D}_{x}+\frac{3}{2}\left(u_{x}-2 v_{x}\right) \mathrm{l} .
\end{aligned}
$$

Note that this Lax pair is given in [9, 42].

### 6.4. The Drinfel'd-Sokolov-Wilson equations

We consider a one-parameter family of the Drinfel'd-Sokolov-Wilson (DSW) equations

$$
\begin{equation*}
u_{t}+3 v v_{x}=0, \quad v_{t}+2 u v_{x}+\alpha u_{x} v+2 v_{3 x}=0, \tag{44}
\end{equation*}
$$

where $\alpha$ is a nonzero parameter. The system with $\alpha=1$ was first proposed by Drinfel'd and Sokolov [12, 13] and Wilson [42]. It can be obtained [26] as a reduction of the Kadomtsev-Petviashvili equation (a two-dimensional version of the KdV equation).

We may assign weights $W\left(\partial_{t}\right)=3, W(u)=2$ and $W(v)=2$. Thus we have the same weight system as the KdV equation and the coupled system above. There are no Lax pairs for this system with $\mathcal{L}$ of order $2,3,4$ or 5 which inherit this scaling symmetry.

There are no solutions for $W(\mathcal{L})=6$ except for $\alpha=1$. In that case

$$
\begin{aligned}
\mathcal{L}= & \mathrm{D}_{x}^{6}+2 u \mathrm{D}_{x}^{4}+\left(4 u_{x}-3 v_{x}\right) \mathrm{D}_{x}^{3}+\left(\frac{9}{2}\left(u_{2 x}-v_{2 x}\right)+u^{2}-v^{2}\right) \mathrm{D}_{x}^{2} \\
& +\left(\frac{5}{2}\left(u_{3 x}-v_{3 x}\right)+2\left(u u_{x}-v v_{x}\right)+u_{x} v-u v_{x}\right) \mathrm{D}_{x} \\
& +\frac{1}{4}\left(2\left(u_{4 x}-v_{4 x}\right)+2(u+v)\left(u_{2 x}-v_{2 x}\right)+u_{x}^{2}-v_{x}^{2}\right) \mathrm{I} \\
\mathcal{M}= & \mathrm{D}_{x}^{3}+u \mathrm{D}_{x}-\frac{1}{2}\left(3 v_{x}-u_{x}\right) \mathrm{I} .
\end{aligned}
$$

The DSW system (44) is known to have infinitely many conservation laws when $\alpha=1$ and is completely integrable [12, 42]. This is the Lax pair given in [42].

| Parameter <br> ratios <br> $\left(\frac{\alpha}{\gamma^{2}}, \frac{\beta}{\gamma}\right)$ | Commonly <br> used values <br> $(\alpha, \beta, \gamma)$ | Equation name | Lax pair <br> references |
| :---: | :---: | :---: | :---: |

Special cases of the fifth-order family (45) of KdV-type equations.

## 7. Classification of fifth-order KdV-like equations

For an equation or system with parameters, the algorithm described in Section 5 can be used to find the necessary conditions on the parameters so that the PDE has a Lax pair and therefore may be completely integrable.

Consider the family of fifth-order KdV-type equations with three parameters

$$
\begin{equation*}
u_{t}+\alpha u^{2} u_{x}+\beta u_{x} u_{x x}+\gamma u u_{3 x}+u_{5 x}=0 . \tag{45}
\end{equation*}
$$

This family includes several well-known completely integrable equations.
Replacing $u$ by $\frac{u}{\gamma}$, it is clear that only the ratios $\frac{\alpha^{2}}{\gamma}$ and $\frac{\beta}{\gamma}$ matter. We continue with (45) for an easier comparison with the results in the literature. The special cases of (45) shown in the table are extensively discussed in the literature [18, 22, $29,36]$. Only the first three equations are completely integrable. Ito's equation is not completely integrable but has an unusual set of conservation laws [18, 23].

We wish to determine which members, if any, have a Lax pair, with $\mathcal{L}$ of second order, which may then be amenable to a (standard) inverse scattering transform based on a quadratic eigenvalue problem. Kaup [27] has considered this family with respect to a cubic eigenvalue problem (that is $\mathcal{L}$ is a third order operator).

Uniformity of weights implies that $W\left(\partial_{t}\right)=5$. The first kinematic constraint is

$$
2 \mathrm{D}_{x} g_{4}-5 c_{5} \mathrm{D}_{x} f_{1}=0
$$

In this situation we may need or wish to give the parameters weight. If this is the case, there may be a weight 1 constant. Therefore the solution to this constraint is

$$
g_{4}=\frac{5}{2} c_{5} f_{1}+c_{4}
$$

where $c_{4}$ is a constant of integration of weight 1 . After all four kinematic constraints
are solved, we have

$$
\begin{aligned}
\mathcal{L}= & \mathrm{D}_{x}^{2}+f_{1} \mathrm{D}_{x}+f_{0} \mathrm{I} \\
\mathcal{M}= & c_{5} \mathrm{D}_{x}^{5}+\left(\frac{5}{2} f_{1}+c_{4}\right) \mathrm{D}_{x}^{4}+\left(\frac{5}{8} c_{5}\left(6 \mathrm{D}_{x} f_{1}+3 f_{1}^{2}+4 f_{0}\right)+2 c_{4} f_{1}+c_{3}\right) \mathrm{D}_{x}^{3} \\
& +\left(\frac{5}{16} c_{5}\left(12 \mathrm{D}_{x}^{2} f_{1}+10 \mathrm{D}_{x} f_{1}^{2}+12 \mathrm{D}_{x} f_{0}+f_{1}^{3}+12 f_{1} f_{0}\right)+c_{4}\left(2 \mathrm{D}_{x} f_{1}+f_{1}^{2}+2 f_{0}\right)\right. \\
& \left.+\frac{3}{2} c_{3} f_{1}+c_{2}\right) \mathrm{D}_{x}^{2}+\left(\frac { 5 } { 1 2 8 } c _ { 5 } \left(48 f_{0} \mathrm{D}_{x} f_{1}+96 f_{1} \mathrm{D}_{x} f_{0}+4 \mathrm{D}_{x} f_{1}^{3}+24 f_{1}^{2} f_{0}\right.\right. \\
& \left.+20\left(\mathrm{D}_{x} f_{1}\right)^{2}+40 f_{1} \mathrm{D}_{x}^{2} f_{1}+24 \mathrm{D}_{x}^{3} f_{1}+80 \mathrm{D}_{x}^{2} f_{0}+48 f_{0}^{2}-f_{1}^{4}\right) \\
& +c_{4}\left(2 \mathrm{D}_{x} f_{0}+f_{1} \mathrm{D}_{x} f_{1}+\mathrm{D}_{x}^{2} f_{1}+2 f_{1} f_{0}\right)+\frac{3}{8} c_{3}\left(4 f_{0}+f_{1}^{2}+2 \mathrm{D}_{x} f_{1}\right) \\
& \left.+c_{2} f_{1}+c_{1}\right) \mathrm{D}_{x}+g_{0} \mathrm{l}
\end{aligned}
$$

For brevity, we omit the two dynamical equations.
We now need to make a choice for the remaining weights. The obvious choice is $W(u)=2$. With this choice, $\alpha, \beta$ and $\gamma$ all have weight zero. Therefore the constants of integration, $c_{1}, \ldots, c_{4}$, are all zero which simplifies the Lax pair dramatically. The only non-trivial solution occurs when $\alpha=\frac{3}{10} \gamma^{2}, \beta=2 \gamma$ which corresponds to the fifth-order KdV equation due to Lax [31]. The Lax pair is

$$
\begin{aligned}
\mathcal{L} & =D_{x}^{2}+\frac{1}{10} \gamma u \mathrm{I} \\
\mathcal{M} & =-16 \mathrm{D}_{x}^{5}-4 \gamma u \mathrm{D}_{x}^{3}-6 \gamma u_{x} \mathrm{D}_{x}^{2}-\gamma\left(5 u_{x x}+\frac{3}{10} \gamma u^{2}\right) \mathrm{D}_{x}-\gamma\left(\frac{3}{2} u_{3 x}+\frac{3}{10} \gamma u u_{x}\right) \mathrm{I} .
\end{aligned}
$$

In [7], it is shown that all scalar evolution equations, which have the form of a conservation law, have a Lax pair with a second order $\mathcal{L}$. Such Lax pairs can be found if we choose the weights $W(u)=1, W(\alpha)=2, W(\beta)=1$ and $W(\gamma)=1$. In this case, the constants of integration may not be zero.

For weight 3, we obtain non-trivial solutions for the Sawada-Kotera and KaupKupershmidt equations. For the Sawada-Kotera equation $\left(\alpha=\frac{1}{5} \gamma^{2}, \beta=\gamma\right)[8,37]$ there are two solutions:

$$
\begin{aligned}
& \text { Case I: } \\
& \\
& \text { Case II: } \\
& \qquad \begin{aligned}
\mathcal{L} & =D_{x}^{3}+\frac{1}{5} \gamma u \mathrm{D}_{x} \\
\mathcal{M} & =9 \mathrm{D}_{x}^{5}+3 \gamma u \mathrm{D}_{x}^{3}+3 \gamma u_{x} \mathrm{D}_{x}^{2}+\gamma\left(\frac{1}{5} \gamma u^{2}+2 u_{2 x}\right) \mathrm{D}_{x} \\
\mathcal{L} & =\mathrm{D}_{x}^{3}+\frac{1}{5} \gamma u \mathrm{D}_{x}+\frac{1}{5} \gamma u_{x} \mathcal{I}, \\
\mathcal{M} & =9 \mathrm{D}_{x}^{5}+3 \gamma u \mathrm{D}_{x}^{3}+6 \gamma u_{x} \mathrm{D}_{x}^{2}+\gamma\left(\frac{1}{5} \gamma u^{2}+5 u_{2 x}\right) \mathrm{D}_{x} \\
& \\
&
\end{aligned} \quad \begin{aligned}
& 2 \gamma\left(\frac{1}{5} \gamma u u_{x}+u_{3 x}\right) \mathcal{I} .
\end{aligned}
\end{aligned}
$$

The first Lax pair is given in $[10,15]$. We cannot find any reference to the second Lax pair in the literature.

The Kaup-Kupershmidt equation $\left(\alpha=\frac{1}{5} \gamma^{2}, \beta=\frac{5}{2} \gamma\right)$ [27] has a single Lax pair:

$$
\begin{aligned}
\mathcal{L} & =D_{x}^{3}+\frac{1}{5} \gamma u D_{x}+\frac{1}{10} \gamma u_{x} \mathcal{I} \\
\mathcal{M} & =9 D_{x}^{5}+3 \gamma u D_{x}^{3}+\frac{9}{2} \gamma u_{x} D_{x}^{2}+\gamma\left(\frac{1}{5} \gamma u^{2}+\frac{7}{2} u_{2 x}\right) D_{x}+\gamma\left(\frac{1}{5} \gamma u u_{x}+u_{3 x}\right) \mathcal{I}
\end{aligned}
$$

which is given in [15].

## 8. Conclusions

The algorithm described in this paper can be easily implemented in Mathematica or Maple. Therein lies its value; it gives a quick method to "test the waters" with a new system of equations. If the equations do not have a scaling symmetry, or the scaling symmetry does not yield a Lax pair, then weighted parameters may be introduced. A new assignment of weights may lead to a Lax pair. The "focus on the equation" of our approach is a marked contrast to existing work where integrable systems have, by and large, been developed from geometric considerations (for example, the use of the Drinfel'd-Sokolov construction [12, 13]).

The question of an appropriate system of weights is non-trivial. As noted above, all members of the three parameter family of fifth-order KdV-like equations have a Lax pair with a second order $\mathcal{L}$. The question naturally arises as to which of these Lax pairs are useful. Can, for example, a criteria be developed that would guarantee an infinite family of local conservations laws?

## Dedication

This paper is dedicated to the memory of Alan Jeffrey. As a Ph.D. student, one of us (WH) was first introduced to the mathematics of nonlinear waves through Alan's seminal paper on Nonlinear Wave Propagation published in Zeitschrift für Angewandte Mechanik und Mathematik 58, T38-56 (1978). With Alan's passing we have lost a researcher, educator, and expositor par excellence.

## Acknowledgements

This material is based in part upon research supported by the National Science Foundation (NSF) under Grant No. CCF-0830783. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of NSF.

WH is grateful for the hospitality and support of the Department of Computer Engineering at Turgut Özal University (Keçiören, Ankara, Turkey) where code for Lax pair computations was further developed.

MH would like the thank the Department of Applied Mathematics and Statistics, Colorado School of Mines for their hospitality while this work was completed.

Undergraduate students Oscar Aguilar, Sara Clifton, William "Tony" McCollom, and graduate student Jacob Rezac are thanked for their help with this project.
